

Removal of OrbeSeal® post-calving

Correct administration of OrbeSeal is essential for correct and complete removal – adherence to best practice minimises the risks of any OrbeSeal residues being present in the milk in early lactation.

- 1** To effectively remove OrbeSeal, take the top of the teat, pinch tight and hand strip the entire quarter ten to twelve times prior to first milking. Repeat until all evidence of product has been removed.
- 2** Strip and check the foremilk carefully for the first few milkings for any evidence of remaining particles. Adhere to withdrawal times for individual products - milk into a dump bucket for the appropriate time before returning to the main milking system. It is recommended that users observe the guideline to not use milk for human consumption for the first four days post partum.
- 3** Foremilk and/or mastitis filters should be examined closely as best practice during every milking. The milk sock and filter canister should be inspected for residues after every milking and replaced as required.

Industry standard plant wash-up procedure and employing an in-line filter or filter sock during wash-up will further reduce the risks of particles of OrbeSeal being found in milk sent for processing.
